

Elements Of Data Science - F2023

Week 4: Hypothesis Testing

10/2/2023

TODOs

- Readings
 - PDSH Chap 5: What is Machine Learning and Introduction to Scikit-Learn
 - PDSH Chap 5 In Depth: Linear Regression
 - PDSH Chap 5 In Depth: Decision Trees and Random Forests
 - Recommended PML Chap 3
 - Optional PML Chap 2
 - Optional PDSH Chap 5 In Depth: Support Vector Machines
- Quiz 3: due today, Oct 2nd, 11:59pm ET via Gradescope
- Quiz 4: due Monday Oct 9th, 11:59pm ET via Gradescope
- HW1: due Friday Oct 13th 11:59pm E via Gradescope
 - *Make sure to indicate on which page each question output is displayed*

Additional Resources

- Statistical Rules of Thumb, Gerald van Belle [Chapter 2 online](#)
- On the use of p-values
 - [The ASA's Statement on p-Values: Context, Process, and Purpose](#)
 - [Moving to a World Beyond “ \$p < 0.05\$ ”](#)
 - [“The 2019 ASA Guide to P-values and Statistical Significance: Don't Say What You Don't Mean” \(Some Recommendations\)\(ii\).](#)

Today

- Confidence Intervals
- Hypothesis Testing
- Multi-Armed Bandit (MAB)

Questions?

Environment Setup

Environment Setup

```
In [1]: 1 import numpy as np
        2 import pandas as pd
        3 import matplotlib.pyplot as plt
        4 import seaborn as sns
        5
        6 sns.set_style('darkgrid')
        7
        8 %matplotlib inline
```

Confidence Intervals and Hypothesis Testing

- Random Sampling
- Confidence Intervals
- Hypothesis Testing
- Permutation Tests
- A/B Tests
- p-values
- Multi-Armed Bandit

Questions and More Questions

- Have web conversions gone up?
- Which ad generates more sales?
- Which headline generates more clicks?
- Did the number of "likes" change?

Example: What can we say about the trip distance of an average taxi trip in Jan 2017?

Example: What can we say about the trip distance of an average taxi trip in Jan 2017?

```
In [2]: 1 df_taxi = (  
2         pd.read_csv('../data/yellowcab_demo_withdaycategories.csv',  
3                     header=1,  
4                     parse_dates=['pickup_datetime', 'dropoff_datetime'])  
5         .assign(  
6             weekpart = lambda df_: df_.is_weekend.apply(lambda x: 'Weekend' if x else 'Weekday'),  
7         )  
8         .loc[:, ['trip_distance', 'is_weekend', 'weekpart']]  
9         .dropna()  
10    )  
11    print(df_taxi.shape)  
12    display(df_taxi.head(5))
```

(1000, 3)

	trip_distance	is_weekend	weekpart
0	0.89	False	Weekday
1	2.70	True	Weekend
2	1.41	True	Weekend
3	0.40	False	Weekday
4	2.30	False	Weekday

Mini Probability Review

- **Random Variable**
 - takes values from an associated probability distribution
 - Ex: trip_distance
- **Distribution**
 - describes probability of values of a Random Variable
- **$P(x)$: Probability**
 - probability of seeing x , takes value in $[0,1]$
 - Ex: $P(\text{trip_distance} > 1)$
- **$P(x \mid y)$: Conditional Probability**
 - probability of seeing x , given some y
 - Ex: $P(\text{trip_distance} > 1 \mid \text{is_weekend} == \text{True})$

Population Distributions and Sampling

- "The World" or "Ground Truth"
 - Ex: The length of taxi rides
- "A Sample" or "Our Data"
 - Ex: The length of taxi rides we saw in Jan 2017

Population Distributions and Sampling

- **Population Distribution:** The actual distribution out in the world
 - Ex: Actual distribution of taxi trip lengths
- **Random Sample:** Our observations of the true population distribution
 - We hope this does not differ systematically from the true distribution
 - Ex: The taxi trip lengths recorded in Jan 2017
- **Sample Size (n):** The number of observations, the larger the better
 - Ex: We saw 1,000 trips

Population Dists and Sampling

- **Population Mean vs. Sample Mean:**
 - Ex: The true mean trip length (μ) vs the one we observed (\bar{x})
- **Population Std. Dev. vs Sample Std. Dev.:**
 - Ex: The true spread of trip length (σ) vs the one we observed (s)
- **Sample Statistic:**
 - eg. mean, median, standard deviation
 - Ex: We're interested in mean trip length
- **Sampling Distribution:**
 - Distribution of the sample statistic
 - Ex: How is mean trip length distributed if we were to repeat our experiment many times?

Things To Know First

- sample size
- shape (skewed?, multimodal?)
- location (central tendencies)
- spread (variance, standard deviation, IQR)

Sampling From the Population

Sampling From the Population

```
In [3]: 1 trip_distance_sample = df_taxi.trip_distance.sample(
2         n=50,                # our sample size
3         random_state=123,    # needed for reproducability
4         replace=False        # sample without replacement
5     )
6
7 print(trip_distance_sample.describe().round(2))
8 print()
9 print(f"sample skew = {trip_distance_sample.skew().round(2)}")
```

```
count      50.00
mean        2.14
std         2.56
min         0.30
25%         0.91
50%         1.60
75%         2.19
max         17.30
Name: trip_distance, dtype: float64

sample skew = 4.55
```

Plot the distribution of our Sample

Plot the distribution of our Sample

```
In [4]: 1 fig,ax = plt.subplots(2,1,figsize=(12,8),sharex=True)
        2 sns.histplot(x=trip_distance_sample, ax=ax[0]);
        3 sns.boxplot(x=trip_distance_sample, ax=ax[1]);
```

Define the Sample Statistic

Define the Sample Statistic

```
In [5]: 1 trip_distance_sample_xbar = trip_distance_sample.mean()  
        2 print(f'sample mean: {trip_distance_sample_xbar:0.2f}')
```

```
sample mean: 2.14
```

Define the Sample Statistic

```
In [5]: 1 trip_distance_sample_xbar = trip_distance_sample.mean()  
        2 print(f'sample mean: {trip_distance_sample_xbar:0.2f}')
```

```
sample mean: 2.14
```

- Is this sample statistic a good approximation?
- Let's take more samples!

Generate Samples and Plot Distribution of Sample Stat.

Generate Samples and Plot Distribution of Sample Stat.

```
In [6]: 1 sample_means = []  
        2 for i in range(1000):  
        3     sample_mean = df_taxi.trip_distance.sample(n=50,random_state=i).mean()  
        4     sample_means.append(sample_mean)
```

Generate Samples and Plot Distribution of Sample Stat.

```
In [6]: 1 sample_means = []  
2 for i in range(1000):  
3     sample_mean = df_taxi.trip_distance.sample(n=50,random_state=i).mean()  
4     sample_means.append(sample_mean)
```

```
In [7]: 1 ax = sns.histplot(x=sample_means)  
2 ax.set_xlabel('sample_means');  
3 ax.set_ylabel('frequency');  
4 ax.axvline(trip_distance_sample_xbar,color='red');
```

Generate Samples and Plot Distribution of Sample Stat.

```
In [6]: 1 sample_means = []
2 for i in range(1000):
3     sample_mean = df_taxi.trip_distance.sample(n=50,random_state=i).mean()
4     sample_means.append(sample_mean)
```

```
In [7]: 1 ax = sns.histplot(x=sample_means)
2 ax.set_xlabel('sample_means');
3 ax.set_ylabel('frequency');
4 ax.axvline(trip_distance_sample_xbar,color='red');
```

But what if we can't generate additional samples? **Bootstrap Confidence Intervals**

Confidence Intervals

Typically we only have one sample from the population (experimental results, survey results, etc.)

Confidence Intervals

Typically we only have one sample from the population (experimental results, survey results, etc.)

```
In [8]: 1 n_trip = trip_distance_sample.shape[0]  
        2 n_trip
```

```
Out[8]: 50
```

Confidence Intervals

Typically we only have one sample from the population (experimental results, survey results, etc.)

```
In [8]: 1 n_trip = trip_distance_sample.shape[0]
        2 n_trip
```

Out[8]: 50

```
In [9]: 1 trip_distance_sample_xbar = trip_distance_sample.mean()
        2 print(f'sample mean: {trip_distance_sample_xbar:0.2f}')
```

sample mean: 2.14

Confidence Intervals

Typically we only have one sample from the population (experimental results, survey results, etc.)

```
In [8]: 1 n_trip = trip_distance_sample.shape[0]
        2 n_trip
```

Out[8]: 50

```
In [9]: 1 trip_distance_sample_xbar = trip_distance_sample.mean()
        2 print(f'sample mean: {trip_distance_sample_xbar:0.2f}')
```

sample mean: 2.14

- What is the spread of our sample statistic?
- What other values would it be reasonable to observe?

Plotting Confidence Intervals with Seaborn

Plotting Confidence Intervals with Seaborn

```
In [10]: 1 fig,ax = plt.subplots(1,1,figsize=(12,4))
2
3 sns.barplot(x=trip_distance_sample,
4             estimator=np.mean, # default sample statistic
5             ci=95,            # default 95% CI
6             n_boot=1000,      # default number of bootstrap samples
7             color='c',
8             );
```

/var/folders/78/vhnqkq8n45dd4gj4f5qx8yb00000gn/T/ipykernel_42210/3208664956.py:3: FutureWarning:

The `ci` parameter is deprecated. Use `errorbar=('ci', 95)` for the same effect.

```
sns.barplot(x=trip_distance_sample,
```

Plotting Confidence Intervals with Seaborn

```
In [10]: 1 fig,ax = plt.subplots(1,1,figsize=(12,4))
2
3 sns.barplot(x=trip_distance_sample,
4             estimator=np.mean, # default sample statistic
5             ci=95,           # default 95% CI
6             n_boot=1000,     # default number of bootstrap samples
7             color='c',
8             );
```

/var/folders/78/vhnqkq8n45dd4gj4f5qx8yb00000gn/T/ipykernel_42210/3208664956.py:3: FutureWarning:

The `ci` parameter is deprecated. Use `errorbar=('ci', 95)` for the same effect.

```
sns.barplot(x=trip_distance_sample,
```

- How are these confidence intervals generated from only one sample?

Generate Confidence Intervals

Bootstrapping: sampling with replacement

Bootstrap Confidence Interval: create confidence interval using bootstrap samples

Generate Confidence Intervals

Bootstrapping: sampling with replacement

Bootstrap Confidence Interval: create confidence interval using bootstrap samples

1. draw a random sample of size n from the data
2. record the sample statistic from this random sample
3. repeat 1 and 2 many times
4. for an $x\%$ CI, find the trim points to remove $\frac{1}{2} \left(1 - \frac{x}{100} \right)$ of the data from both ends
5. those trim points are the endpoints of the the $x\%$ bootstrap CI

1. & 2. Draw a Random Sample and Record Statistic

1. & 2. Draw a Random Sample and Record Statistic

```
In [11]: 1 # 1. draw a random sample with replacement
          2 random_sample = trip_distance_sample.sample(
          3     n=trip_distance_sample.shape[0], # same size as number of observations (or frac=1)
          4     replace=True,                    # sample with replacement
          5     random_state=123                 # for reproducibility
          6 )
          7 random_sample.head(3)

In [ ]: 1
```

Plotting Distribution of Sample Means With CIs

Plotting Distribution of Sample Means With CIs

```
In [19]: 1 fig,ax = plt.subplots(1,1,figsize=(12,8))
2 ax = sns.histplot(sample_means)
3 ax.axvline(df_taxi.trip_distance.mean(), color='r');
4 ax.axvline(ci[0],color='k');ax.axvline(ci[1],color='k')
5 ax.set_xlabel('bootstrap sample means');
6 ax.set_ylabel('frequency');
```

Interpreting CIs

- **Does NOT tell us:** "the probability that the true value lies within that interval"
- **Tells us:** something about the variability of this statistic
- **Tells us:** how confident we should be that our parameter lies in the interval

If confidence intervals are constructed using a given confidence level from an infinite number of independent sample statistics, the proportion of those intervals that contain the true value of the parameter will be equal to the confidence level.

Interpreting Cls

Interpreting CIs

```
In [20]: 1 fig,ax = plt.subplots(1,1,figsize=(12,6))  
2 sns.barplot(x='is_weekend',y='trip_distance',data=df_taxi);
```

Questions re Cls?

Hypothesis Testing

- Ex: Is the average trip longer on weekends compared to weekdays?
- Ex: Does one advertisement lead to more sales than another?
- **Null Hypothesis: H_0**
 - the thing we're observing is happening due to random chance
 - there are no differences between two groups
- **Alternative Hypothesis: H_1**
 - the thing we're observing is happening not due to random chance
 - there is a difference between two groups
- Experiment: given data, do we **accept or reject H_0** ?
 - Ex: can we say the difference between average trip on weekdays vs. weekends isn't random?

Errors in Hypothesis Tests

		Reality	
		True	False
Measured/ Perceived	True	Correct 😊	Type I False Positive
	False	Type II False Negative	Correct 😊

https://www.gilliganondata.com/wp-content/uploads/2009/08/TypeI_TypeII1.JPG

Errors in Hypothesis Tests

<https://flowingdata.com/wp-content/uploads/2014/05/Type-I-and-II-errors1-620x465.jpg>

Significance and Power

Significance and Power

- $P(\text{reject } H_0 \mid H_0 \text{ true})$ = **Significance** of test or **p-value** (Type I Error)
 - Probability of saying **things aren't by chance when they are**
 - Ex: Saying trips on weekends are longer, when the difference *is* random
 - Ex: Saying Ad A was correlated with more sales, when the difference *is* random

Significance and Power

- $P(\text{reject } H_0 \mid H_0 \text{ true})$ = **Significance** of test or **p-value** (Type I Error)
 - Probability of saying **things aren't by chance when they are**
 - Ex: Saying trips on weekends are longer, when the difference *is* random
 - Ex: Saying Ad A was correlated with more sales, when the difference *is* random
- $P(\text{reject } H_0 \mid H_1 \text{ true})$ = **Power** of test (1-Type II Error)
 - Probability of saying **things aren't by chance when they aren't**
 - Ex: Saying trips on weekends are longer, when the difference *is not* random
 - Ex: Saying Ad A was correlated with more sales, when the difference *is not* random

Ex: Trip-Distance by Weekday vs. Weekend

Ex: Trip-Distance by Weekday vs. Weekend

- Question: Is the average trip_distance different on weekdays vs weekends?

```
In [21]: 1 sns.barplot(x='is_weekend',y='trip_distance',data=df_taxi);
```

Ex: Trip-Distance by Weekday vs. Weekend, Define the Metric

- **Metric:** the measure we're interested in
 - Ex: We're interested in a difference of means: Weekday - Weekend

Ex: Trip-Distance by Weekday vs. Weekend, Define the Metric

- **Metric:** the measure we're interested in
 - Ex: We're interested in a difference of means: Weekday - Weekend

```
In [22]: 1 mean_weekend = df_taxi.loc[df_taxi.is_weekend, 'trip_distance'].mean()  
2 mean_weekday = df_taxi.loc[~df_taxi.is_weekend, 'trip_distance'].mean()  
3 observed_trip_metric = mean_weekend - mean_weekday  
4 print(f'observed metric: {observed_trip_metric.round(2)}')
```

```
observed metric: 0.58
```

Ex: Trip-Distance by Weekday vs. Weekend, Define the Metric

- **Metric:** the measure we're interested in
 - Ex: We're interested in a difference of means: Weekday - Weekend

```
In [22]: 1 mean_weekend = df_taxi.loc[df_taxi.is_weekend, 'trip_distance'].mean()  
2 mean_weekday = df_taxi.loc[~df_taxi.is_weekend, 'trip_distance'].mean()  
3 observed_trip_metric = mean_weekend - mean_weekday  
4 print(f'observed metric: {observed_trip_metric.round(2)}')
```

```
observed metric: 0.58
```

- Is this surprising? Should we reject the null?
 - Assuming that H_0 is true, is this observation surprising?

Permutation Test

- How do we generate additional samples of the difference in means? Resampling!
- Need to repeatedly split the data into two groups and take the difference in means
- One way to do this: combine, permute (reorder) and split

Permutation Test

1. combine groups together (assume H_0 is true)
2. permute (reorder) observations
3. create new groups (same sizes as original groups)
4. calculate metric
5. repeat many times
6. see where our original observation falls in the distribution of sample statistics

Ex: Avg Trip-Distance on Weekday vs. Weekend, Permutation Test

Ex: Avg Trip-Distance on Weekday vs. Weekend, Permutation Test

```
In [23]: 1 # 0. get group sizes
          2 n_weekend = df_taxi.is_weekend.sum()
          3 n_weekday = (~df_taxi.is_weekend).sum()
          4 print(f'{n_weekend=} {n_weekday=}')
          5 assert n_weekday + n_weekend == df_taxi.shape[0]
```

```
n_weekend=150 n_weekday=850
```

Ex: Avg Trip-Distance on Weekday vs. Weekend, Permutation Test

```
In [23]: 1 # 0. get group sizes
          2 n_weekend = df_taxi.is_weekend.sum()
          3 n_weekday = (~df_taxi.is_weekend).sum()
          4 print(f'{n_weekend=} {n_weekday=}')
          5 assert n_weekday + n_weekend == df_taxi.shape[0]
```

- This looks like a normal distribution?
- Why would that be?
- How can we turn this into a Standard Normal distribution...

Aside: Central Limit Theorem

Aside: Central Limit Theorem

If all samples are randomly drawn from the same sample population:

For reasonably large samples (usually $n \geq 30$), the distribution of sample mean \bar{x} is normal regardless of the distribution of X .

The sampling distribution of \bar{x} becomes approximately normal as the the sample size n gets large.

Ex:

- X = trip_distance
- \bar{x} = mean trip_distance
- n = 50

Aside: What is Normal?

Aside: What is Normal?

distribution defined by mean (μ) and standard deviation (σ)

$$N(x; \mu, \sigma) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

PDF (Probability Density Function):

- function of a continuous random variable that provides a relative likelihood of seeing a particular sample of a random variable.

Aside: Properties of a Normal Distribution

<https://towardsdatascience.com/understanding-the-68-95-99-7-rule-for-a-normal-distribution-b7b7cbf760c2>

Aside: Scipy

- Routines for numerical integration, interpolation, optimization, linear algebra, and **statistics**.
- Useful for sampling from random distributions and equation based testing

Aside: Scipy

5 ax.axvline(observed_trip_metric, color='r');
```

Why Use Permutation Tests?

- data can be numeric or boolean (ex. temperature, conversion, etc)
- group sizes can be different
- assumptions about normally distributed data are not needed (with many permutations)

A/B Tests

- Do one of two treatments produce superior results?
 - testing two prices to determine which generates more profit
 - testing two web headlines to determine which produces more clicks
 - testing two advertisements to see which produces more conversions
- Often Used Test Statistics
 - difference in means
 - difference in counts

Ex: Webpages and Sales

- Question: Which webpage leads to more sales?
- Potential Issue: what if sales are large but infrequent?
- **Proxy Variable:** stand in for true value of interest
 - Ex: Assume 'time on page' is correlated with sales

Ex: Webpages and Sales

- Question: Which webpage leads to more sales?
- Potential Issue: what if sales are large but infrequent?
- **Proxy Variable:** stand in for true value of interest
 - Ex: Assume 'time on page' is correlated with sales

```
In [35]: 1 session_times = pd.read_csv('../data/web_page_data.csv')
          2 print(session_times.shape)
          3
          4 session_times.head(3)
```

```
(36, 2)
```

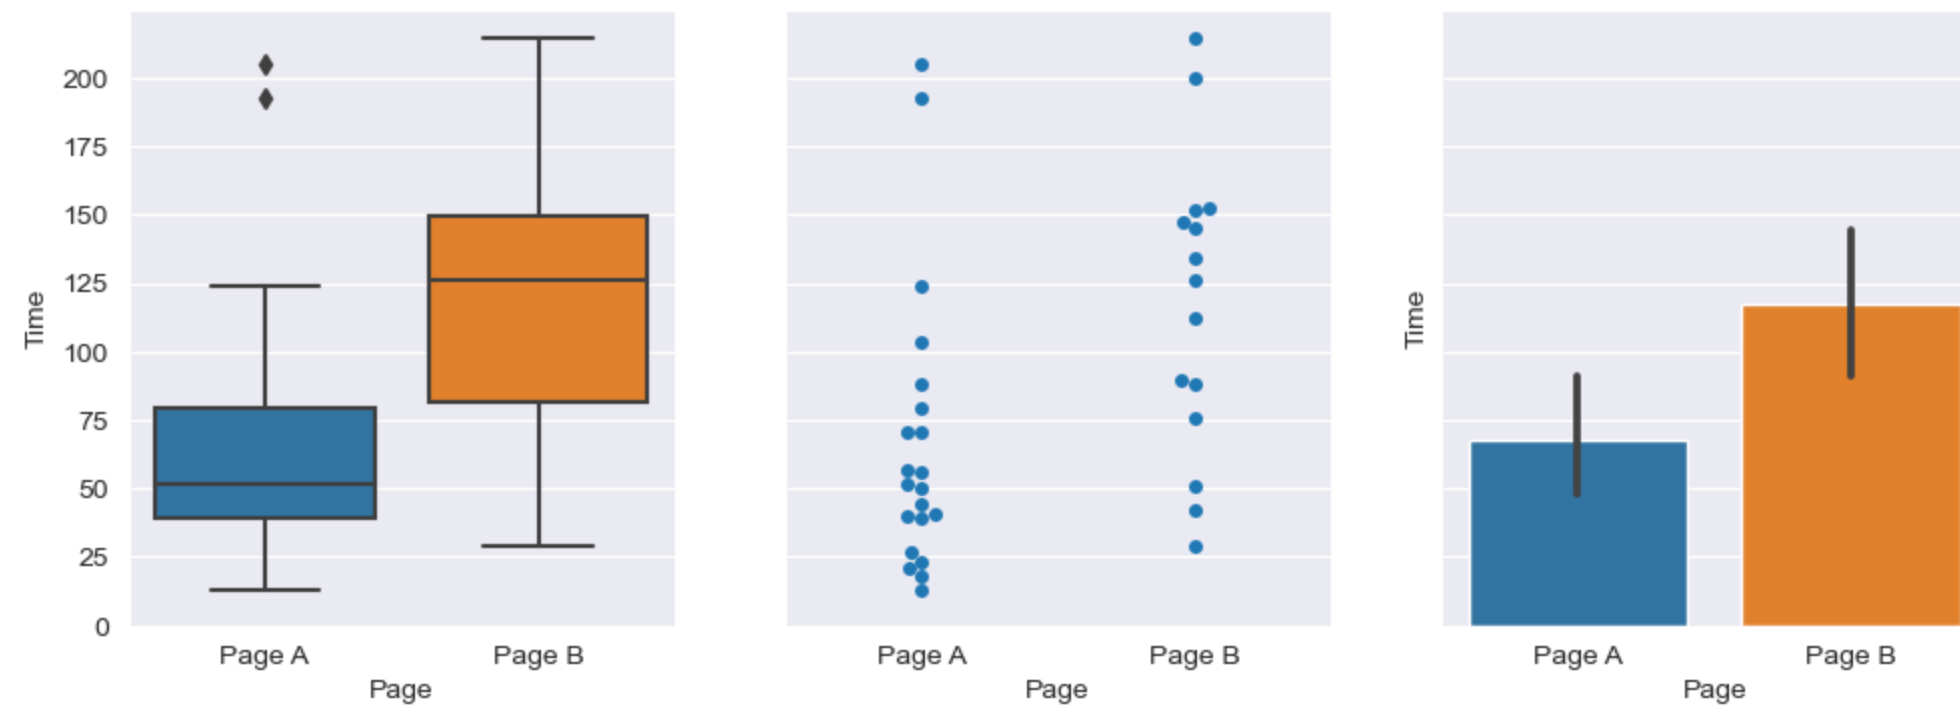

```
Out[35]:
```

	Page	Time
0	Page A	12.6
1	Page B	151.7
2	Page A	21.0

- does mean : $P(\text{data} \mid H_0 \text{ is true})$
- does NOT mean : $P(H_0 \text{ is not true} \mid \text{data})$
- Our question about significance becomes:

"How often did we see a value as or more extreme than our observed metric?"

One-Tailed vs Two-Tailed Tests

<https://towardsdatascience.com/one-tailed-or-two-tailed-test-that-is-the-question-1283387f631c?gi=9568e456cd13>

Choosing One-Tailed vs Two-Tailed

- Do we have a strong reason for a one-directional question? One-Tailed
 - Ex: H_0 is "difference is less than or equal to 0"
 - Need a strong reason
- Otherwise? Two-tailed
 - Ex: H_0 is "there is no real difference between groups"
 - More conservative
 - Usually a better choice

Calculating p for Two-Tailed Test

Calculating p for Two-Tailed Test

```
In [47]: 1 # find absolute values greater than our observed_metric  
        2 ad_gt = np.abs(rand_mean_ad_diffs) >= np.abs(observed_ad_metric)
```

Calculating p for Two-Tailed Test

```
In [47]: 1 # find absolute values greater than our observed_metric
        2 ad_gt = np.abs(rand_mean_ad_diffs) >= np.abs(observed_ad_metric)
```

```
In [48]: 1 # how many are greater than or equal to?
        2 num_ad_gt = ad_gt.sum()
        3
        4 # proportion of total that are as or more extreme
        5 p = num_ad_gt / len(rand_mean_ad_diffs)
        6 print(f'{p = :}')
```

```
p = 0.0078
```

One-Tailed Test Example

One-Tailed Test Example

```
In [49]: 1 # one-tailed test  
        2 sum(np.array(rand_mean_ad_diffs) <= observed_ad_metric) / len(rand_mean_ad_diffs)
```

```
Out[49]: 0.0037
```

One-Tailed Test Example

```
In [49]: 1 # one-tailed test  
        2 sum(np.array(rand_mean_ad_diffs) <= observed_ad_metric) / len(rand_mean_ad_diffs)
```

```
Out[49]: 0.0037
```

Note that this is less than our Two-Tailed value!

One-Tailed Test Example

```
In [49]: 1 # one-tailed test  
2 sum(np.array(rand_mean_ad_diffs) <= observed_ad_metric) / len(rand_mean_ad_diffs)
```

Out[49]: 0.0037

Note that this is less than our Two-Tailed value!

```
In [50]: 1 # two-tailed test  
2 sum(np.abs(rand_mean_ad_diffs) >= np.abs(observed_ad_metric)) / len(rand_mean_ad_diffs)
```

Out[50]: 0.0078

Equation Based Hypothesis Test: t-Test

Equation Based Hypothesis Test: t-Test

- based on the Student-t distribution
- more involved to describe
- works for numeric data (can't use it for the next example)

Equation Based Hypothesis Test: t-Test

- based on the Student-t distribution
- more involved to describe
- works for numeric data (can't use it for the next example)

```
In [51]: 1 # using our session_times example
          2 t = sp.stats.ttest_ind(session_times[session_times.Page == 'Page A'].Time.values,
          3                           session_times[session_times.Page == 'Page B'].Time.values,
          4                           equal_var=False)
          5 print(f'{t.pvalue = :0.3f}')
```

```
t.pvalue = 0.010
```

Equation Based Hypothesis Test: t-Test

- based on the Student-t distribution
- more involved to describe
- works for numeric data (can't use it for the next example)

```
In [51]: 1 # using our session_times example
          2 t = sp.stats.ttest_ind(session_times[session_times.Page == 'Page A'].Time.values,
          3                           session_times[session_times.Page == 'Page B'].Time.values,
          4                           equal_var=False)
          5 print(f'{t.pvalue = :0.3f}')
```

```
t.pvalue = 0.010
```

- close to the 0.008 value we found via permutation test

Choosing α

- alpha (α): significance level
 - What we compare our p-value to
 - Best to choose this before calculating metrics
 - Probability of rejecting the null when it is true (Type I Error)
- Common values:
 - .1 (Error 1 out of 10 times)
 - .05 (Error 1 out of 20 times)
 - .01 (Error 1 out of 100 times)
- Should depend on how bad a Type I (False Positive) Error is

Another Example: Price vs Conversion

- Does Price A lead to higher conversions than Price B?
- **Conversion:** Turning a visit into a sale
- H_0 : conversions for Price A \leq conversions for Price B
 - Price A does not lead to more conversions
- H_1 : conversions for Price A $>$ conversions for Price B
 - Price A leads to more conversions

Another Example: Price vs Conversion

- Does Price A lead to higher conversions than Price B?
- **Conversion:** Turning a visit into a sale
- H_0 : conversions for Price A \leq conversions for Price B
 - Price A does not lead to more conversions
- H_1 : conversions for Price A $>$ conversions for Price B
 - Price A leads to more conversions

```
In [52]: 1 # Counts of observations
          2 df = pd.DataFrame({'Price A': [200, 23539],
          3                       'Price B': [182, 22406]},
          4                       index=['Conversion', 'No Conversion'])
          5 df
```

Out[52]:

	Price A	Price B
Conversion	200	182
No Conversion	23539	22406

Another Example: Price vs Conversion Continued

- Metric of Interest?
 - difference in percent conversion

Another Example: Price vs Conversion Continued

- Metric of Interest?
 - difference in percent conversion

```
In [53]: 1 pct_conv = df.loc['Conversion'] / df.sum(axis=0) * 100  
        2 pct_conv.round(2)
```

```
Out[53]: Price A    0.84  
        Price B    0.81  
        dtype: float64
```

Another Example: Price vs Conversion Continued

- Metric of Interest?
 - difference in percent conversion

```
In [53]: 1 pct_conv = df.loc['Conversion'] / df.sum(axis=0) * 100
          2 pct_conv.round(2)
```

```
Out[53]: Price A    0.84
          Price B    0.81
          dtype: float64
```

```
In [54]: 1 diff_pct_conv = pct_conv['Price A'] - pct_conv['Price B']
          2 print(f'{diff_pct_conv.round(3)}%')
```

```
0.037%
```

Another Example: Price vs Conversion Continued

- First: Choose our α : 0.05
- Reminder of Permutation Test:
 0. get group sizes
 1. combine groups together
 2. permute observations
 3. create two new groups (same sizes as originals)
 4. calculate metric
 5. repeat many times
 6. see where our original observation falls

Another Example: Price vs Conversion Continued

- What are our samples?
 - 1 = Conversion
 - 0 = No conversion
- How many samples are there?

Another Example: Price vs Conversion Continued

- What are our samples?
 - 1 = Conversion
 - 0 = No conversion
- How many samples are there?

```
In [55]: 1 n = df.sum().sum()  
        2 n
```

```
Out[55]: 46327
```

          5                           alternative='two-sided')
          6 print(f'{p = :0.3f}')
```

p = 0.662

Statistically Significant?

The ASA Statement on p-Values: Context, Process, and Purpose Wasserstein & Lazar, 09 Jun 2016]

- Don't base your conclusions solely on whether an association or effect was found to be “statistically significant” (i.e., the p-value passed some arbitrary threshold such as $p < 0.05$).
- Don't believe an association/effect **exists** just because it **was statistically significant**.
- Don't believe an association/effect **is absent** just because it **was not stat. significant**.
- Don't believe that your p-value:
 1. gives the **probability that chance alone** produced the observed association/effect or
 2. the probability that your **test hypothesis is true**.]
- Don't conclude anything about **scientific or practical importance** based on statistical significance (or lack thereof).

Statistically Significant?

- Moving to a World Beyond “ $p < 0.05$ ” Wasserstein, Schirm & Lazar, 20 Mar 2019
 - Try to avoid “Statistically Significant”
 - “Accept uncertainty. Be thoughtful, open, and modest.” Remember “**ATOM.**”

Statistically Significant?

- Moving to a World Beyond “ $p < 0.05$ ” Wasserstein, Schirm & Lazar, 20 Mar 2019
 - Try to avoid “Statistically Significant”
 - “Accept uncertainty. Be thoughtful, open, and modest.” Remember “**ATOM**.”
- ATOM
 - **A**: Seek better measures, more sensitive designs, larger samples
 - **T**: Begin with clearly expressed objectives
 - **T**: Ask "What are the practical implications?"
 - **O**:: Be open/transparent in analysis and communication
 - **M**: Accept limitations, assumptions, reproduction, recognizing differences in stakes

Issues with Multiple Testing

- p-hacking: keep trying comparisons till you find something that works
- multiple tests: the more tests you run, the more likely a Type 1 Error
- One simple solution:
 - **Bonferonni correction** $\frac{\alpha}{m}$ where m is the number of tests

Comparing More Than 2 Groups

- ANOVA
 - need more stats than we have time for
- Multi-Armed Bandit (MAB)
 - can compare many distributions
 - don't need to make assumptions about underlying distributions
 - can also be used for early stopping of experiment

Multi-Armed Bandit

Question: Which arm should we pull?

Greedy MAB

greedy: do something simple that heads towards the goal

1. pull arm with highest payout

But what if there's a better choice, we just haven't seen it yet?

Exploration Vs Exploitation

- **Exploration:** There might be a better arm
 - keep choosing different arms randomly
- **Exploitation:** We want to make use of the best
 - keep pulling the best arm

ϵ -Greedy MAB

- choose a small epsilon (ϵ) between 0 and 1

ϵ -Greedy MAB

- choose a small epsilon (ϵ) between 0 and 1
1. generate random number between 0 and 1
 2. if $< \epsilon$, choose arm randomly
 3. if $\geq \epsilon$, choose best arm
 4. GOTO 1

MAB Example

- We have three ads
- We don't know how often each will lead to a response
- We need to decide which ad to add to each page request

MAB Example

- We have three ads
- We don't know how often each will lead to a response
- We need to decide which ad to add to each page request

```
In [65]: 1 # creating two ads (distributions) with unknown response rate
          2 np.random.seed(13)
          3 ad_A = sp.stats.bernoulli(p=np.random.rand())
          4 ad_B = sp.stats.bernoulli(p=np.random.rand())
          5 ad_C = sp.stats.bernoulli(p=np.random.rand())
```

MAB Example

- We have three ads
- We don't know how often each will lead to a response
- We need to decide which ad to add to each page request

```
In [65]: 1 # creating two ads (distributions) with unknown response rate
          2 np.random.seed(13)
          3 ad_A = sp.stats.bernoulli(p=np.random.rand())
          4 ad_B = sp.stats.bernoulli(p=np.random.rand())
          5 ad_C = sp.stats.bernoulli(p=np.random.rand())
```

- We'll use an ϵ -greedy MAB to decide which ad to show

MAB Example

- We have three ads
- We don't know how often each will lead to a response
- We need to decide which ad to add to each page request

```
In [65]: 1 # creating two ads (distributions) with unknown response rate
          2 np.random.seed(13)
          3 ad_A = sp.stats.bernoulli(p=np.random.rand())
          4 ad_B = sp.stats.bernoulli(p=np.random.rand())
          5 ad_C = sp.stats.bernoulli(p=np.random.rand())
```

- We'll use an ϵ -greedy MAB to decide which ad to show

```
In [66]: 1 # epsilon probability
          2 epsilon = 0.40
```

- Which arm seems best?

```
In [74]: 1 rates = ' '.join([f"{label}:{np.mean(reward).round(1)}" for label,reward in zip(labels,rewards)])  
        2 print(f"conversion rates: {rates}")
```

```
conversion rates: A:0.3 B:0.5 C:0.9
```

- Did we pick the best one?

MAB Example Continued

- Which arm seems best?

```
In [74]: 1 rates = ' '.join([f"{label}:{np.mean(reward).round(1)}" for label,reward in zip(labels,rewards)])  
        2 print(f"conversion rates: {rates}")
```

```
conversion rates: A:0.3 B:0.5 C:0.9
```

- Did we pick the best one?

```
In [75]: 1 ground_truth_rates = ' '.join([f"{label}:{arm.pmf(1).round(1)}" for label,arm in zip(labels,arms)])  
        2 print(f'ground truth: {ground_truth_rates}')
```

```
ground truth: A:0.8 B:0.2 C:0.8
```

MAB Variations

- Thompson's Sampling: uses Bayesian approach
- UCB1: maximize expected reward using Upper Confidence Bounds
- UCBC: Upper Confidence Bound with Clusters
- ...
